PAP1.PAU.02.US PATENT

Amendments to the Abstract:

Please replace the Abstract with the following amended Abstract:

The invention uses one inductor, which is comprised-formed of one, two or a few twisted or parallel conductors, and exposes the a sample object in a pulsed and damped alternating magnetic field B-(B) without necessarily the employment of a second, constant intensity, magnetic field. In this way, the nuclei and for the electrons of the sample object sample object are activated, in the presence of a non-constant magnetic field B-(B), that gets infinite negative and positive values between successive damped positive and negative values, crossing through the zero value during a magnetic pulse. Thus, a wide nuclear NMR and Electronic EPR Multiple — Resonance electronic EPR multiple — resonance of the sample object; is achieved.
